Alignment – Related terms: frame geometry, track tension. Definition: The process of adjusting the treadmill's belt and deck to ensure the running surface is straight and parallel to the frame. Proper alignment prevents premature wear of the belt and reduces motor strain. Example: A technician uses a straightedge and a tension gauge to verify that the belt tracks centrally without drifting. Practical application: Aligning the treadmill before performing a calibration ensures that measurement data reflect true performance. Challenge: Misaligned frames can cause false calibration readings, leading to inaccurate speed settings.
